`mwparserfromhell` (the *MediaWiki Parser from Hell*) is a Python package that provides an easy-to-use and outrageously powerful parser for [MediaWiki](#) wikicode. It supports Python 2 and Python 3.

Developed by [Earwig](#) with help from [Σ](#).

# INSTALLATION

The easiest way to install the parser is through the [Python Package Index](#), so you can install the latest release with `pip install mwparserfromhell` ([get pip](#)). Alternatively, get the latest development version:

```
git clone git://github.com/earwig/mwparserfromhell.git
cd mwparserfromhell
python setup.py install
```

You can run the comprehensive unit testing suite with `python setup.py test`.

# CONTENTS

## 2.1 Usage

Normal usage is rather straightforward (where `text` is page text):

```
>>> import mwparserfromhell
>>> wikicode = mwparserfromhell.parse(text)
```

`wikicode` is a `mwparserfromhell.Wikicode` object, which acts like an ordinary `unicode` object (or `str` in Python 3) with some extra methods. For example:

```
>>> text = "I has a template! {{foo|bar|baz|eggs=spam}} See it?"
>>> wikicode = mwparserfromhell.parse(text)
>>> print wikicode
I has a template! {{foo|bar|baz|eggs=spam}} See it?
>>> templates = wikicode.filter_templates()
>>> print templates
[ '{{foo|bar|baz|eggs=spam}}' ]
>>> template = templates[0]
>>> print template.name
foo
>>> print template.params
['bar', 'baz', 'eggs=spam']
>>> print template.get(1).value
bar
>>> print template.get("eggs").value
spam
```

Since every node you reach is also a `Wikicode` object, it's trivial to get nested templates:

```
>>> code = mwparserfromhell.parse("{{foo|this {{includes a|template}}}}")
>>> print code.filter_templates()
[ '{{foo|this {{includes a|template}}}}' ]
>>> foo = code.filter_templates()[0]
>>> print foo.get(1).value
this {{includes a|template}}
>>> print foo.get(1).value.filter_templates()[0]
{{includes a|template}}
>>> print foo.get(1).value.filter_templates()[0].get(1).value
template
```

Additionally, you can include nested templates in `filter_templates()` by passing `recursive=True`:

```
>>> text = "{{foo|{{bar}}={{baz|{{spam}}}}}}"
>>> mwparservfromhell.parse(text).filter_templates(recursive=True)
['{{foo|{{bar}}={{baz|{{spam}}}}}}', '{{bar}}', '{{baz|{{spam}}}}', '{{spam}}']
```

Templates can be easily modified to add, remove, or alter params. Wikicode can also be treated like a list with `append()`, `insert()`, `remove()`, `replace()`, and more:

```
>>> text = "{{cleanup}} 'Foo' is a [[bar]]. {{uncategorized}}"
>>> code = mwparservfromhell.parse(text)
>>> for template in code.filter_templates():
...     if template.name == "cleanup" and not template.has_param("date"):
...         template.add("date", "July 2012")
...
>>> print code
{{cleanup|date=July 2012}} 'Foo' is a [[bar]]. {{uncategorized}}
>>> code.replace("{{uncategorized}}", "{{bar-stub}}")
>>> print code
{{cleanup|date=July 2012}} 'Foo' is a [[bar]]. {{bar-stub}}
>>> print code.filter_templates()
['{{cleanup|date=July 2012}}', '{{bar-stub}}']
```

You can then convert `code` back into a regular `unicode` object (for saving the page!) by calling `unicode()` on it:

```
>>> text = unicode(code)
>>> print text
{{cleanup|date=July 2012}} 'Foo' is a [[bar]]. {{bar-stub}}
>>> text == code
True
```

(Likewise, use `str(code)` in Python 3.)

For more tips, check out [Wikicode's full method list](#) and the [list of Nodes](#).

## 2.2 Integration

`mwparservfromhell` is used by and originally developed for [EarwigBot](#); Page objects have a `parse()` method that essentially calls `mwparservfromhell.parse()` on `get()`.

If you're using PyWikipedia, your code might look like this:

```
import mwparservfromhell
import wikipedia as pywikibot
def parse(title):
    site = pywikibot.get_site()
    page = pywikibot.Page(site, title)
    text = page.get()
    return mwparservfromhell.parse(text)
```

If you're not using a library, you can parse templates in any page using the following code (via the API):

```
import json
import urllib
import mwparservfromhell
API_URL = "http://en.wikipedia.org/w/api.php"
def parse(title):
    raw = urllib.urlopen(API_URL, data).read()
    res = json.loads(raw)
```

```
text = res["query"]["pages"].values()[0]["revisions"][0]["*"]
return mwparserfromhell.parse(text)
```

## 2.3 mwparserfromhell

### 2.3.1 mwparserfromhell Package

#### **mwparserfromhell** Package

**mwparserfromhell** (the MediaWiki Parser from Hell) is a Python package that provides an easy-to-use and outrageously powerful parser for [MediaWiki](#) wikicode.

```
mwparserfromhell.__init__.parse(text)
Short for Parser.parse().
```

#### **compat** Module

Implements support for both Python 2 and Python 3 by defining common types in terms of their Python 2/3 variants. For example, `str` is set to `unicode` on Python 2 but `str` on Python 3; likewise, `bytes` is `str` on 2 but `bytes` on 3. These types are meant to be imported directly from within the parser's modules.

#### **smart\_list** Module

This module contains the `SmartList` type, as well as its `_ListProxy` child, which together implement a list whose sublists reflect changes made to the main list, and vice-versa.

```
class mwparserfromhell.smart_list.SmartList(iterable=None)
Bases: list
```

Implements the `list` interface with special handling of sublists.

When a sublist is created (by `list[i:j]`), any changes made to this list (such as the addition, removal, or replacement of elements) will be reflected in the sublist, or vice-versa, to the greatest degree possible. This is implemented by having sublists - instances of the `_ListProxy` type - dynamically determine their elements by storing their slice info and retrieving that slice from the parent. Methods that change the size of the list also change the slice info. For example:

```
>>> parent = SmartList([0, 1, 2, 3])
>>> parent
[0, 1, 2, 3]
>>> child = parent[2:]
>>> child
[2, 3]
>>> child.append(4)
>>> child
[2, 3, 4]
>>> parent
[0, 1, 2, 3, 4]

append(item)
L.append(object) – append object to end

extend(item)
L.extend(iterable) – extend list by appending elements from the iterable
```

```
insert(index, item)
    L.insert(index, object) – insert object before index

pop([index]) → item – remove and return item at index (default last).
    Raises IndexError if list is empty or index is out of range.

remove(item)
    L.remove(value) – remove first occurrence of value. Raises ValueError if the value is not present.

reverse()
    L.reverse() – reverse IN PLACE

sort(cmp=None, key=None, reverse=None)
    L.sort(cmp=None, key=None, reverse=False) – stable sort IN PLACE; cmp(x, y) -> -1, 0, 1

class mwparserfromhell.smart_list._ListProxy(parent, sliceinfo)
Bases: list

Implement the list interface by getting elements from a parent.

This is created by a SmartList object when slicing. It does not actually store the list at any time; instead, whenever the list is needed, it builds it dynamically using the _render() method.

append(item)
    L.append(object) – append object to end

count(value) → integer – return number of occurrences of value

extend(item)
    L.extend(iterable) – extend list by appending elements from the iterable

index(value[, start[, stop]]) → integer – return first index of value.
    Raises ValueError if the value is not present.

insert(index, item)
    L.insert(index, object) – insert object before index

pop([index]) → item – remove and return item at index (default last).
    Raises IndexError if list is empty or index is out of range.

remove(item)
    L.remove(value) – remove first occurrence of value. Raises ValueError if the value is not present.

reverse()
    L.reverse() – reverse IN PLACE

sort(cmp=None, key=None, reverse=None)
    L.sort(cmp=None, key=None, reverse=False) – stable sort IN PLACE; cmp(x, y) -> -1, 0, 1
```

## string\_mixin Module

This module contains the `StringMixin` type, which implements the interface for the `unicode` type (`str` on py3k) in a dynamic manner.

```
class mwparserfromhell.string_mixin.StringMixin
Implement the interface for unicode/str in a dynamic manner.

To use this class, inherit from it and override the __unicode__() method (same on py3k) to return the string representation of the object. The various string methods will operate on the value of __unicode__() instead of the immutable self like the regular str type.

capitalize() → unicode
    Return a capitalized version of S, i.e. make the first character have upper case and the rest lower case.
```

**center** (*width[, fillchar ]*) → unicode

Return S centered in a Unicode string of length width. Padding is done using the specified fill character (default is a space)

**count** (*sub[, start[, end ]*]) → int

Return the number of non-overlapping occurrences of substring sub in Unicode string S[start:end]. Optional arguments start and end are interpreted as in slice notation.

**decode** ([*encoding[, errors ]*]) → string or unicode

Decodes S using the codec registered for encoding. encoding defaults to the default encoding. errors may be given to set a different error handling scheme. Default is ‘strict’ meaning that encoding errors raise a UnicodeDecodeError. Other possible values are ‘ignore’ and ‘replace’ as well as any other name registered with codecs.register\_error that is able to handle UnicodeDecodeErrors.

**encode** ([*encoding[, errors ]*]) → string or unicode

Encodes S using the codec registered for encoding. encoding defaults to the default encoding. errors may be given to set a different error handling scheme. Default is ‘strict’ meaning that encoding errors raise a UnicodeEncodeError. Other possible values are ‘ignore’, ‘replace’ and ‘xmlcharrefreplace’ as well as any other name registered with codecs.register\_error that can handle UnicodeEncodeErrors.

**endswith** (*suffix[, start[, end ]*]) → bool

Return True if S ends with the specified suffix, False otherwise. With optional start, test S beginning at that position. With optional end, stop comparing S at that position. suffix can also be a tuple of strings to try.

**expandtabs** ([*tabsize*]) → unicode

Return a copy of S where all tab characters are expanded using spaces. If tabsize is not given, a tab size of 8 characters is assumed.

**find** (*sub[, start[, end ]*]) → int

Return the lowest index in S where substring sub is found, such that sub is contained within S[start:end]. Optional arguments start and end are interpreted as in slice notation.

Return -1 on failure.

**format** (\**args*, \*\**kwargs*) → unicode

Return a formatted version of S, using substitutions from args and kwargs. The substitutions are identified by braces ({‘ and ‘}).

**index** (*sub[, start[, end ]*]) → int

Like S.find() but raise ValueError when the substring is not found.

**isalnum** () → bool

Return True if all characters in S are alphanumeric and there is at least one character in S, False otherwise.

**isalpha** () → bool

Return True if all characters in S are alphabetic and there is at least one character in S, False otherwise.

**isdecimal** () → bool

Return True if there are only decimal characters in S, False otherwise.

**isdigit** () → bool

Return True if all characters in S are digits and there is at least one character in S, False otherwise.

**islower** () → bool

Return True if all cased characters in S are lowercase and there is at least one cased character in S, False otherwise.

**isnumeric** () → bool

Return True if there are only numeric characters in S, False otherwise.

**isspace()** → bool  
Return True if all characters in S are whitespace and there is at least one character in S, False otherwise.

**istitle()** → bool  
Return True if S is a titlecased string and there is at least one character in S, i.e. upper- and titlecase characters may only follow uncased characters and lowercase characters only cased ones. Return False otherwise.

**isupper()** → bool  
Return True if all cased characters in S are uppercase and there is at least one cased character in S, False otherwise.

**join(iterable)** → unicode  
Return a string which is the concatenation of the strings in the iterable. The separator between elements is S.

**ljust(width[, fillchar])** → int  
Return S left-justified in a Unicode string of length width. Padding is done using the specified fill character (default is a space).

**lower()** → unicode  
Return a copy of the string S converted to lowercase.

**lstrip([chars])** → unicode  
Return a copy of the string S with leading whitespace removed. If chars is given and not None, remove characters in chars instead. If chars is a str, it will be converted to unicode before stripping

**partition(sep) -> (head, sep, tail)**  
Search for the separator sep in S, and return the part before it, the separator itself, and the part after it. If the separator is not found, return S and two empty strings.

**replace(old, new[, count])** → unicode  
Return a copy of S with all occurrences of substring old replaced by new. If the optional argument count is given, only the first count occurrences are replaced.

**rfind(sub[, start[, end]])** → int  
Return the highest index in S where substring sub is found, such that sub is contained within S[start:end].  
Optional arguments start and end are interpreted as in slice notation.  
  
Return -1 on failure.

**rindex(sub[, start[, end]])** → int  
Like S.rfind() but raise ValueError when the substring is not found.

**rjust(width[, fillchar])** → unicode  
Return S right-justified in a Unicode string of length width. Padding is done using the specified fill character (default is a space).

**rpartition(sep) -> (head, sep, tail)**  
Search for the separator sep in S, starting at the end of S, and return the part before it, the separator itself, and the part after it. If the separator is not found, return two empty strings and S.

**rsplit([sep[, maxsplit]])** → list of strings  
Return a list of the words in S, using sep as the delimiter string, starting at the end of the string and working to the front. If maxsplit is given, at most maxsplit splits are done. If sep is not specified, any whitespace string is a separator.

**rstrip([chars])** → unicode  
Return a copy of the string S with trailing whitespace removed. If chars is given and not None, remove characters in chars instead. If chars is a str, it will be converted to unicode before stripping

**split**(*[sep[, maxsplit ]]*) → list of strings

Return a list of the words in S, using sep as the delimiter string. If maxsplit is given, at most maxsplit splits are done. If sep is not specified or is None, any whitespace string is a separator and empty strings are removed from the result.

**splittlines**(*[keepends ]*) → list of strings

Return a list of the lines in S, breaking at line boundaries. Line breaks are not included in the resulting list unless keepends is given and true.

**startswith**(*prefix[, start[, end ]]*) → bool

Return True if S starts with the specified prefix, False otherwise. With optional start, test S beginning at that position. With optional end, stop comparing S at that position. prefix can also be a tuple of strings to try.

**strip**(*[chars ]*) → unicode

Return a copy of the string S with leading and trailing whitespace removed. If chars is given and not None, remove characters in chars instead. If chars is a str, it will be converted to unicode before stripping

**swapcase**() → unicode

Return a copy of S with uppercase characters converted to lowercase and vice versa.

**title**() → unicode

Return a titlecased version of S, i.e. words start with title case characters, all remaining cased characters have lower case.

**translate**(*table*) → unicode

Return a copy of the string S, where all characters have been mapped through the given translation table, which must be a mapping of Unicode ordinals to Unicode ordinals, Unicode strings or None. Unmapped characters are left untouched. Characters mapped to None are deleted.

**upper**() → unicode

Return a copy of S converted to uppercase.

**zfill**(*width*) → unicode

Pad a numeric string S with zeros on the left, to fill a field of the specified width. The string S is never truncated.

## utils Module

This module contains accessory functions that wrap around existing ones to provide additional functionality.

**mwparserfromhell.utils.parse\_anything**(*value*)

Return a [Wikicode](#) for *value*, allowing multiple types.

This differs from `mwparserfromhell.parse()` in that we accept more than just a string to be parsed. Unicode objects (strings in py3k), strings (bytes in py3k), integers (converted to strings), None, existing [Node](#) or [Wikicode](#) objects, as well as an iterable of these types, are supported. This is used to parse input on-the-fly by various methods of [Wikicode](#) and others like [Template](#), such as `wikicode.insert()` or setting `template.name`.

## wikicode Module

**class mwparserfromhell.wikicode.Wikicode**(*nodes*)

Bases: `mwparserfromhell.string_mixin.StringMixIn`

A Wikicode is a container for nodes that operates like a string.

Additionally, it contains methods that can be used to extract data from or modify the nodes, implemented in an interface similar to a list. For example, `index()` can get the index of a node in the list, and `insert()` can

add a new node at that index. The `filter()` series of functions is very useful for extracting and iterating over, for example, all of the templates in the object.

**append(*value*)**

Insert *value* at the end of the list of nodes.

*value* can be anything parsable by `parse_anything()`.

**filter(*recursive=False, matches=None, flags=50, forcetype=None*)**

Return a list of nodes within our list matching certain conditions.

This is equivalent to calling `list()` on `ifilter()`.

**filter\_links(*recursive=False, matches=None, flags=50*)**

Return a list of wikilink nodes.

This is equivalent to calling `list()` on `ifilter_links()`.

**filter\_tags(*recursive=False, matches=None, flags=50*)**

Return a list of tag nodes.

This is equivalent to calling `list()` on `ifilter_tags()`.

**filter\_templates(*recursive=False, matches=None, flags=50*)**

Return a list of template nodes.

This is equivalent to calling `list()` on `ifilter_templates()`.

**filter\_text(*recursive=False, matches=None, flags=50*)**

Return a list of text nodes.

This is equivalent to calling `list()` on `ifilter_text()`.

**get(*index*)**

Return the *index*th node within the list of nodes.

**get\_sections(*flat=True, matches=None, levels=None, flags=50, include\_headings=True*)**

Return a list of sections within the page.

Sections are returned as `Wikicode` objects with a shared node list (implemented using `SmartList`) so that changes to sections are reflected in the parent `Wikicode` object.

With *flat* as `True`, each returned section contains all of its subsections within the `Wikicode`; otherwise, the returned sections contain only the section up to the next heading, regardless of its size. If *matches* is given, it should be a regex to matched against the titles of section headings; only sections whose headings match the regex will be included. If *levels* is given, it should be a = list of integers; only sections whose heading levels are within the list will be returned. If *include\_headings* is `True`, the section's literal `Heading` object will be included in returned `Wikicode` objects; otherwise, this is skipped.

**get\_tree()**

Return a hierarchical tree representation of the object.

The representation is a string makes the most sense printed. It is built by calling `_get_tree()` on the `Wikicode` object and its children recursively. The end result may look something like the following:

```
>>> text = "Lorem ipsum {{foo|bar|{{baz}}|spam=eggs}}"
>>> print mwparservfromhell.parse(text).get_tree()
Lorem ipsum
{
    foo
    |
    = bar
    |
    = {
        1
        =
        bar
        |
        = 2
        =
        { {
```

```
        baz
    } }
|  spam
= eggs
} }
```

**ifilter**(*recursive=False*, *matches=None*, *flags=50*, *forcetype=None*)

Iterate over nodes in our list matching certain conditions.

If *recursive* is True, we will iterate over our children and all descendants of our children, otherwise just our immediate children. If *matches* is given, we will only yield the nodes that match the given regular expression (with `re.search()`). The default flags used are `re.IGNORECASE`, `re.DOTALL`, and `re.UNICODE`, but custom flags can be specified by passing *flags*. If *forcetype* is given, only nodes that are instances of this type are yielded.

**ifilter\_links**(*recursive=False*, *matches=None*, *flags=50*)

Iterate over wikilink nodes.

This is equivalent to `ifilter()` with *forcetype* set to `Wikilink`.

**ifilter\_tags**(*recursive=False*, *matches=None*, *flags=50*)

Iterate over tag nodes.

This is equivalent to `ifilter()` with *forcetype* set to `Tag`.

**ifilter\_templates**(*recursive=False*, *matches=None*, *flags=50*)

Iterate over template nodes.

This is equivalent to `ifilter()` with *forcetype* set to `Template`.

**ifilter\_text**(*recursive=False*, *matches=None*, *flags=50*)

Iterate over text nodes.

This is equivalent to `ifilter()` with *forcetype* set to `Text`.

**index**(*obj*, *recursive=False*)

Return the index of *obj* in the list of nodes.

Raises `ValueError` if *obj* is not found. If *recursive* is True, we will look in all nodes of ours and their descendants, and return the index of our direct descendant node within *our* list of nodes. Otherwise, the lookup is done only on direct descendants.

**insert**(*index*, *value*)

Insert *value* at *index* in the list of nodes.

*value* can be anything parsable by `parse_anything()`, which includes strings or other `Wikicode` or `Node` objects.

**insert\_after**(*obj*, *value*, *recursive=True*)

Insert *value* immediately after *obj* in the list of nodes.

*obj* can be either a string or a `Node`. *value* can be anything parsable by `parse_anything()`. If *recursive* is True, we will try to find *obj* within our child nodes even if it is not a direct descendant of this `Wikicode` object. If *obj* is not in the node list, `ValueError` is raised.

**insert\_before**(*obj*, *value*, *recursive=True*)

Insert *value* immediately before *obj* in the list of nodes.

*obj* can be either a string or a `Node`. *value* can be anything parsable by `parse_anything()`. If *recursive* is True, we will try to find *obj* within our child nodes even if it is not a direct descendant of this `Wikicode` object. If *obj* is not in the node list, `ValueError` is raised.

**nodes**

A list of [Node](#) objects.

This is the internal data actually stored within a [Wikicode](#) object.

**remove (obj, recursive=True)**

Remove *obj* from the list of nodes.

*obj* can be either a string or a [Node](#). If *recursive* is True, we will try to find *obj* within our child nodes even if it is not a direct descendant of this [Wikicode](#) object. If *obj* is not in the node list, [ValueError](#) is raised.

**replace (obj, value, recursive=True)**

Replace *obj* with *value* in the list of nodes.

*obj* can be either a string or a [Node](#). *value* can be anything parsable by [parse\\_anything\(\)](#). If *recursive* is True, we will try to find *obj* within our child nodes even if it is not a direct descendant of this [Wikicode](#) object. If *obj* is not in the node list, [ValueError](#) is raised.

**set (index, value)**

Set the Node at *index* to *value*.

Raises [IndexError](#) if *index* is out of range, or [ValueError](#) if *value* cannot be coerced into one [Node](#). To insert multiple nodes at an index, use [get\(\)](#) with either [remove\(\)](#) and [insert\(\)](#) or [replace\(\)](#).

**strip\_code (normalize=True, collapse=True)**

Return a rendered string without unprintable code such as templates.

The way a node is stripped is handled by the [\\_\\_showtree\\_\\_\(\)](#) method of [Node](#) objects, which generally return a subset of their nodes or None. For example, templates and tags are removed completely, links are stripped to just their display part, headings are stripped to just their title. If *normalize* is True, various things may be done to strip code further, such as converting HTML entities like  $\Sigma$ ,  $\#931;$ , and  $\#x3a3;$  to  $\Sigma$ . If *collapse* is True, we will try to remove excess whitespace as well (three or more newlines are converted to two, for example).

## Subpackages

### nodes Package

**nodes Package** This package contains [Wikicode](#) “nodes”, which represent a single unit of wikitext, such as a Template, an HTML tag, a Heading, or plain text. The node “tree” is far from flat, as most types can contain additional [Wikicode](#) types within them - and with that, more nodes. For example, the name of a [Template](#) is a [Wikicode](#) object that can contain text or more templates.

**class mwparservfromhell.nodes.Node**

Represents the base Node type, demonstrating the methods to override.

[\\_\\_unicode\\_\\_\(\)](#) must be overridden. It should return a unicode or (str in py3k) representation of the node. If the node contains [Wikicode](#) objects inside of it, [\\_\\_iternodes\\_\\_\(\)](#) should be overridden to yield tuples of ([wikicode](#), [node\\_in\\_wikicode](#)) for each node in each [wikicode](#), as well as the node itself (None, self). If the node is printable, [\\_\\_strip\\_\\_\(\)](#) should be overridden to return the printable version of the node - it does not have to be a string, but something that can be converted to a string with [str\(\)](#). Finally, [\\_\\_showtree\\_\\_\(\)](#) can be overridden to build a nice tree representation of the node, if desired, for [get\\_tree\(\)](#).

### argument Module

**class** mwparserfromhell.nodes.argument.\*\*Argument\*\* (*name, default=None*)

Bases: mwparserfromhell.nodes.Node

Represents a template argument substitution, like {{foo}}.

**default**

The default value to substitute if none is passed.

This will be None if the argument wasn't defined with one. The MediaWiki parser handles this by rendering the argument itself in the result, complete braces. To have the argument render as nothing, set default to "" ({{{arg}}}) vs. {{{arg|}}}.

**name**

The name of the argument to substitute.

**comment Module**

**class** mwparserfromhell.nodes.comment.\*\*Comment\*\* (*contents*)

Bases: mwparserfromhell.nodes.Node

Represents a hidden HTML comment, like <!-- foobar -->.

**contents**

The hidden text contained between <!-- and -->.

**heading Module**

**class** mwparserfromhell.nodes.heading.\*\*Heading\*\* (*title, level*)

Bases: mwparserfromhell.nodes.Node

Represents a section heading in wikicode, like == Foo ==.

**level**

The heading level, as an integer between 1 and 6, inclusive.

**title**

The title of the heading, as a Wikicode object.

**html\_entity Module**

**class** mwparserfromhell.nodes.html\_entity.\*\*HTMLEntity\*\* (*value, named=None, hexadecimal=False, hex\_char=u'x'*)

Bases: mwparserfromhell.nodes.Node

Represents an HTML entity, like &nbsp;, either named or unnamed.

**hex\_char**

If the value is hexadecimal, this is the letter denoting that.

For example, the hex\_char of "&#x1234;" is "x", whereas the hex\_char of "&#X1234;" is "X". Lowercase and uppercase x are the only values supported.

**hexadecimal**

If unnamed, this is whether the value is hexadecimal or decimal.

**named**

Whether the entity is a string name for a codepoint or an integer.

For example, &Sigma;, &#931;, and &#x3a3; refer to the same character, but only the first is "named", while the others are integer representations of the codepoint.

**normalize()**

Return the unicode character represented by the HTML entity.

**value**

The string value of the HTML entity.

**tag Module**

**class** mwparsertomhell.nodes.tag.Tag (*type\_*, *tag*, *contents=None*, *attrs=None*, *showtag=True*,  
  *self\_closing=False*, *open\_padding=0*, *close\_padding=0*)

Bases: mwparsertomhell.nodes.Node

Represents an HTML-style tag in wikicode, like <ref>.

**attrs**

The list of attributes affecting the tag.

Each attribute is an instance of [Attribute](#).

**close\_padding**

How much spacing to insert before the last closing >.

**contents**

The contents of the tag, as a [Wikicode](#) object.

**open\_padding**

How much spacing to insert before the first closing >.

**self\_closing**

Whether the tag is self-closing with no content.

**showtag**

Whether to show the tag itself instead of a wikicode version.

**tag**

The tag itself, as a [Wikicode](#) object.

**type**

The tag type.

**template Module**

**class** mwparsertomhell.nodes.template.Template (*name*, *params=None*)

Bases: mwparsertomhell.nodes.Node

Represents a template in wikicode, like {{foo}}.

**add** (*name*, *value*, *showkey=None*, *force\_nonconformity=False*)

Add a parameter to the template with a given *name* and *value*.

*name* and *value* can be anything parsable by `utils.parseAnything()`; pipes (and equal signs, if appropriate) are automatically escaped from *value* where applicable. If *showkey* is given, this will determine whether or not to show the parameter's name (e.g., {{foo|bar}}'s parameter has a name of "1" but it is hidden); otherwise, we'll make a safe and intelligent guess. If *name* is already a parameter, we'll replace its value while keeping the same spacing rules unless *force\_nonconformity* is True. We will also try to guess the dominant spacing convention when adding a new parameter using `_get_spacing_conventions()` unless *force\_nonconformity* is True.

**get** (*name*)

Get the parameter whose name is *name*.

The returned object is a [Parameter](#) instance. Raises [ValueError](#) if no parameter has this name. Since multiple parameters can have the same name, we'll return the last match, since the last parameter is the only one read by the MediaWiki parser.

**has\_param**(*name*, *ignore\_empty=True*)

Return True if any parameter in the template is named *name*.

With *ignore\_empty*, False will be returned even if the template contains a parameter with the name *name*, if the parameter's value is empty. Note that a template may have multiple parameters with the same name.

**name**

The name of the template, as a [Wikicode](#) object.

**params**

The list of parameters contained within the template.

**remove**(*name*, *keep\_field=False*, *force\_no\_field=False*)

Remove a parameter from the template whose name is *name*.

If *keep\_field* is True, we will keep the parameter's name, but blank its value. Otherwise, we will remove the parameter completely unless other parameters are dependent on it (e.g. removing bar from {{foo|bar|baz}} is unsafe because {{foo|baz}} is not what we expected, so {{foo|baz}} will be produced instead), unless *force\_no\_field* is also True. If the parameter shows up multiple times in the template, we will remove all instances of it (and keep one if *keep\_field* is True - that being the first instance if none of the instances have dependents, otherwise that instance will be kept).

## text Module

**class** mwparserfromhell.nodes.text.Text(*value*)

Bases: mwparserfromhell.nodes.Node

Represents ordinary, unformatted text with no special properties.

**value**

The actual text itself.

## wikilink Module

**class** mwparserfromhell.nodes.wikilink.Wikilink(*title*, *text=None*)

Bases: mwparserfromhell.nodes.Node

Represents an internal wikilink, like [[Foo|Bar]].

**text**

The text to display (if any), as a [Wikicode](#) object.

**title**

The title of the linked page, as a [Wikicode](#) object.

## Subpackages

### extras Package

**extras Package** This package contains objects used by [Nodes](#), but are not nodes themselves. This includes the parameters of Templates or the attributes of HTML tags.

#### attribute Module

**class** mwparserfromhell.nodes.extras.attribute.Attribute(*name*, *value=None*, *quoted=True*)

Bases: mwparserfromhell.string\_mixin.StringMixin

Represents an attribute of an HTML tag.

This is used by [Tag](#) objects. For example, the tag <ref name="foo"> contains an Attribute whose name is "name" and whose value is "foo".

**name**

The name of the attribute as a [Wikicode](#) object.

**quoted**

Whether the attribute's value is quoted with double quotes.

**value**

The value of the attribute as a [Wikicode](#) object.

**parameter Module**

**class** mwparserfromhell.nodes.extras.parameter.**Parameter** (*name*, *value*, *showkey=True*)

Bases: [mwparserfromhell.string\\_mixin.StringMixin](#)

Represents a parameter of a template.

For example, the template {{foo|bar|spam=eggs}} contains two Parameters: one whose name is "1", value is "bar", and showkey is False, and one whose name is "spam", value is "eggs", and showkey is True.

**name**

The name of the parameter as a [Wikicode](#) object.

**showkey**

Whether to show the parameter's key (i.e., its "name").

**value**

The value of the parameter as a [Wikicode](#) object.

**parser Package**

**parser Package** This package contains the actual wikicode parser, split up into two main modules: the [tokenizer](#) and the [builder](#). This module joins them together under one interface.

**class** mwparserfromhell.parser.**Parser** (*text*)

Represents a parser for wikicode.

Actual parsing is a two-step process: first, the text is split up into a series of tokens by the [Tokenizer](#), and then the tokens are converted into trees of [Wikicode](#) objects and [Nodes](#) by the [Builder](#).

**parse()**

Return a string as a parsed [Wikicode](#) object tree.

**builder Module**

**class** mwparserfromhell.parser.builder.**Builder**

Combines a sequence of tokens into a tree of [Wikicode](#) objects.

To use, pass a list of [Tokens](#) to the [build\(\)](#) method. The list will be exhausted as it is parsed and a [Wikicode](#) object will be returned.

**\_handle\_argument()**

Handle a case where an argument is at the head of the tokens.

**\_handle\_attribute()**

Handle a case where a tag attribute is at the head of the tokens.

`_handle_comment()`  
Handle a case where a hidden comment is at the head of the tokens.

`_handle_entity()`  
Handle a case where an HTML entity is at the head of the tokens.

`_handle_heading(token)`  
Handle a case where a heading is at the head of the tokens.

`_handle_parameter(default)`  
Handle a case where a parameter is at the head of the tokens.  
*default* is the value to use if no parameter name is defined.

`_handle_tag(token)`  
Handle a case where a tag is at the head of the tokens.

`_handle_template()`  
Handle a case where a template is at the head of the tokens.

`_handle_token(token)`  
Handle a single token.

`_handle_wikilink()`  
Handle a case where a wikilink is at the head of the tokens.

`_pop(wrap=True)`  
Pop the current node list off of the stack.  
If *wrap* is True, we will call `_wrap()` on the list.

`_push()`  
Push a new node list onto the stack.

`_wrap(nodes)`  
Properly wrap a list of nodes in a Wikicode object.

`_write(item)`  
Append a node to the current node list.

`build(tokenlist)`  
Build a Wikicode object from a list tokens and return it.

**contexts Module** This module contains various “context” definitions, which are essentially flags set during the tokenization process, either on the current parse stack (local contexts) or affecting all stacks (global contexts). They represent the context the tokenizer is in, such as inside a template’s name definition, or inside a level-two heading. This is used to determine what tokens are valid at the current point and also if the current parsing route is invalid.

The tokenizer stores context as an integer, with these definitions bitwise OR’d to set them, AND’d to check if they’re set, and XOR’d to unset them. The advantage of this is that contexts can have sub-contexts (as FOO == 0b11 will cover BAR == 0b10 and BAZ == 0b01).

Local (stack-specific) contexts:

- TEMPLATE
  - TEMPLATE\_NAME
  - TEMPLATE\_PARAM\_KEY
  - TEMPLATE\_PARAM\_VALUE
- ARGUMENT

- ARGUMENT\_NAME
- ARGUMENT\_DEFAULT
- WIKILINK
  - WIKILINK\_TITLE
  - WIKILINK\_TEXT
- HEADING
  - HEADING\_LEVEL\_1
  - HEADING\_LEVEL\_2
  - HEADING\_LEVEL\_3
  - HEADING\_LEVEL\_4
  - HEADING\_LEVEL\_5
  - HEADING\_LEVEL\_6
- COMMENT

Global contexts:

- GL\_HEADING

### **tokenizer Module**

**class mwparserfromhell.parser.tokenizer.Tokenizer**

Creates a list of tokens from a string of wikicode.

**END = <object object at 0x2213070>**

**MARKERS = [u'(', u')', u'[', u']', u'<', u'>', u'!', u'=', u'&', u'#', u'\*', u';', u':', u'/', u'~', u'!', u'\n', <object object at 0x2213080>]**

**START = <object object at 0x2213080>**

**\_context**

The current token context.

**\_fail\_route()**

Fail the current tokenization route.

Discards the current stack/context/textbuffer and raises `BadRoute`.

**\_handle\_argument\_end()**

Handle the end of an argument at the head of the string.

**\_handle\_argument\_separator()**

Handle the separator between an argument's name and default.

**\_handle\_heading\_end()**

Handle the end of a section heading at the head of the string.

**\_handle\_template\_end()**

Handle the end of a template at the head of the string.

**\_handle\_template\_param()**

Handle a template parameter at the head of the string.

**\_handle\_template\_param\_value()**

Handle a template parameter's value at the head of the string.

```
_handle_wikilink_end()
    Handle the end of a wikilink at the head of the string.

_handle_wikilink_separator()
    Handle the separator between a wikilink's title and its text.

_parse(context=0)
    Parse the wikicode string, using context for when to stop.

_parse_argument()
    Parse an argument at the head of the wikicode string.

_parse_comment()
    Parse an HTML comment at the head of the wikicode string.

_parse_entity()
    Parse an HTML entity at the head of the wikicode string.

_parse_heading()
    Parse a section heading at the head of the wikicode string.

_parse_template()
    Parse a template at the head of the wikicode string.

_parse_template_or_argument()
    Parse a template or argument at the head of the wikicode string.

_parse_wikilink()
    Parse an internal wikilink at the head of the wikicode string.

_pop(keep_context=False)
    Pop the current stack/context/textbuffer, returning the stack.

    If *keep_context is True, then we will replace the underlying stack's context with the current stack's.

_push(context=0)
    Add a new token stack, context, and textbuffer to the list.

_push_textbuffer()
    Push the textbuffer onto the stack as a Text node and clear it.

_read(delta=0, wrap=False, strict=False)
    Read the value at a relative point in the wikicode.

    The value is read from self._head plus the value of delta (which can be negative). If wrap is False, we will not allow attempts to read from the end of the string if self._head + delta is negative. If strict is True, the route will be failed (with _fail_route()) if we try to read from past the end of the string; otherwise, self.END is returned. If we try to read from before the start of the string, self.START is returned.

_really_parse_entity()
    Actually parse an HTML entity and ensure that it is valid.

_stack
    The current token stack.

_textbuffer
    The current textbuffer.

_verify_safe(unsaferes)
    Verify that there are no unsafe characters in the current stack.

    The route will be failed if the name contains any element of unsaferes in it (not merely at the beginning or end). This is used when parsing a template name or parameter key, which cannot contain newlines.
```

```
_write(token)
    Write a token to the end of the current token stack.

_write_all(tokenlist)
    Write a series of tokens to the current stack at once.

_write_first(token)
    Write a token to the beginning of the current token stack.

_write_text(text)
    Write text to the current textbuffer.

_write_text_then_stack(text)
    Pop the current stack, write text, and then write the stack.

regex = <_sre.SRE_Pattern object at 0x1dc9660>

tokenize(text)
    Build a list of tokens from a string of wikicode and return it.

exception mwparserfromhell.parser.tokenizer.BadRoute
    Raised internally when the current tokenization route is invalid.
```

**tokens Module** This module contains the token definitions that are used as an intermediate parsing data type - they are stored in a flat list, with each token being identified by its type and optional attributes. The token list is generated in a syntactically valid form by the [Tokenizer](#), and then converted into the :py:class:`~.Wikicode` tree by the [Builder](#).

```
class mwparserfromhell.parser.tokens.Token(**kwargs)
    A token stores the semantic meaning of a unit of wikicode.

class mwparserfromhell.parser.tokens.Text(**kwargs)

class mwparserfromhell.parser.tokens.TemplateOpen(**kwargs)

class mwparserfromhell.parser.tokens.TemplateParamSeparator(**kwargs)

class mwparserfromhell.parser.tokens.TemplateParamEquals(**kwargs)

class mwparserfromhell.parser.tokens.TemplateClose(**kwargs)

class mwparserfromhell.parser.tokens.ArgumentOpen(**kwargs)

class mwparserfromhell.parser.tokens.ArgumentSeparator(**kwargs)

class mwparserfromhell.parser.tokens.ArgumentClose(**kwargs)

class mwparserfromhell.parser.tokens.WikilinkOpen(**kwargs)

class mwparserfromhell.parser.tokens.WikilinkSeparator(**kwargs)

class mwparserfromhell.parser.tokens.WikilinkClose(**kwargs)

class mwparserfromhell.parser.tokens.HTMLEntityStart(**kwargs)

class mwparserfromhell.parser.tokens.HTMLEntityNumeric(**kwargs)

class mwparserfromhell.parser.tokens.HTMLEntityHex(**kwargs)

class mwparserfromhell.parser.tokens.HTMLEntityEnd(**kwargs)

class mwparserfromhell.parser.tokens.HeadingStart(**kwargs)

class mwparserfromhell.parser.tokens.HeadingEnd(**kwargs)

class mwparserfromhell.parser.tokens.CommentStart(**kwargs)
```

```
class mwparserfromhell.parser.tokens.CommentEnd (**kwargs)
class mwparserfromhell.parser.tokens.TagOpenOpen (**kwargs)
class mwparserfromhell.parser.tokens.TagAttrStart (**kwargs)
class mwparserfromhell.parser.tokens.TagAttrEquals (**kwargs)
class mwparserfromhell.parser.tokens.TagAttrQuote (**kwargs)
class mwparserfromhell.parser.tokens.TagCloseOpen (**kwargs)
class mwparserfromhell.parser.tokens.TagCloseSelfclose (**kwargs)
class mwparserfromhell.parser.tokens.TagOpenClose (**kwargs)
class mwparserfromhell.parser.tokens.TagCloseClose (**kwargs)
```
